This report is intended to make results of research available at the earliest possible date, but it is not intended to constitute final or formal publication.

Summary

Core samples from the Pennsylvanian Kansas City, Marmaton, and Cherokee Groups were collected from the #1 Douglas County Core Hole (N2 S2 SE SW sec. 8, T. 14 S.-., R. 19 E.; lat. 38.84215°, long. 95.32785°) operated by the Kansas Geological Survey with the aid of a grant from Steve Dixon (Edmond, OK). The well (API # 15-045-21557) was drilled from June 10, 2009, to July 23, 2009, to a depth of 1725 ft (G.L. = 940 ft), with T.D. in the Silurian–Devonian Hunton(?) Group. Core samples of dark shale and coal from this well were analyzed for their desorbed gas content. The samples tested calculate as having the following gas contents:

<i>unit, depth</i>	<i>(desorbed gas)</i>
• Eudora Shale Member, 242' 0" to 242' 8.5"	(no significant gas)
• Muncie Creek Shale Member, 438' 4.5" to 439' 4"	(no significant gas)
• Quivira Shale Member, 474' 2" to 475' 0"	(no significant gas)
• Fontana Shale Member, 513' 0" to 514' 10.5"	(no significant gas)
• Stark Shale Member, 548' 0" to 548' 8"	(no significant gas)
• Hushpuckney Shale Member, 573' 9.5" to 575' 0.5"	(11 scf/ton)
• Nuyaka Creek shale, 757' 6" to 759' 2"	(8 scf/ton)
• Unnamed shale, 765' 0" to 766' 0"	(no significant gas)
• Mulberry coal, 781' 3" to 782' 8"	(12 scf/ton)
• Lexington coal, 816' 2" to 817' 2"	(25 scf/ton)
• Bevier coal, 955' 8" to 956' 9"	(10 scf/ton)
• Croweburg coal, 965' 8" to 966' 2"	(18 scf/ton)
• Mineral coal, 995' 0" to 995' 6"	(19 scf/ton)
• Tebo coal, 1041' 5" to 1042' 11"	(21 scf/ton)
• shale below Tebo coal, 1053' 2" to 1054' 1"	(no significant gas)
• DBj coal, 1180' 6" to 1181' 6"	(34 scf/ton)
• Drywood coal, 1192' 0" to 1193' 2.5"	(45 scf/ton)
• Drywood coal, 1193' 2.5" to 1194' 8.5"	(57 scf/ton)*
• Rowe coal, 1201' 0" to 1202' 5.5"	(51 scf/ton)
• Neutral coal, 1217' 2.5" to 1217' 10.5"	(34 scf/ton)
• Riverton coal, 1271' 1" to 1271' 8"	(39 scf/ton)
• Chattanooga Shale, 1675' 0" to 1676' 0"	(no significant gas)

*71 scf/ton, including residual gas obtained by ball-mill grinding after desorption analysis

The thickest coal beds were the Drywood (32.5 in), Tebo (18 in), Rowe (17.5 in), Mulberry (17 in), Bevier (13 in), Dbj (12 in), and Lexington (12 in). Four coals thinner than 12 in were also encountered.

Background

A grant from Steve Dixon (Edmond, Oklahoma) facilitated the coring of this well in eastern Kansas (Figure 1), and allowed testing of its samples for adsorbed gas. The grant enabled the well to be drilled from the surface to 5 ft in to the top of the Mississippian limestone (i.e., 1382 ft). Deeper drilling was supported by internal funds from the Kansas Geological Survey. The ultimate objective of the hole was the Precambrian basement, but problems with borehole caving and the high likelihood that the coring device might be caught in the hole militated shut down of the operations at 1725 ft.

LOCATION MAP

KGS #1 Douglas County Core Hole and nearby test holes

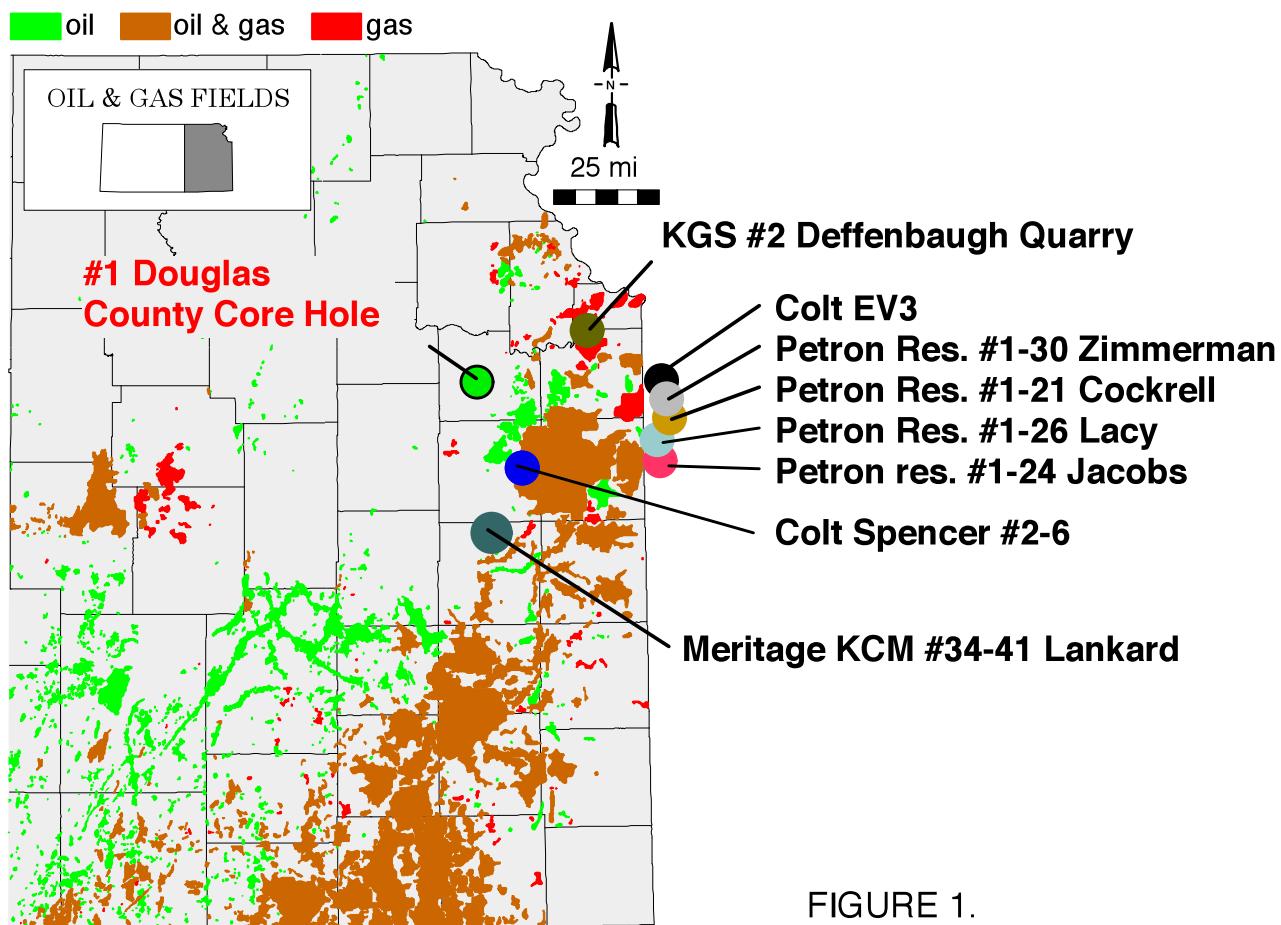

FIGURE 1.

Figure 1—Location map for the #1 Douglas County Core Hole, in relation to other wells in eastern Kansas and western Missouri from which samples were studied for adsorbed gas content.

Procedure

Samples were described and collected for desorption analysis by K. David Newell, LeaAnn Davidson, and Kenneth R. Stalder of the Kansas Geological Survey. The well was cored by Joe Anderson, the Kansas Geological Survey (KGS) driller, and his crew using a new wireline-coring drilling rig recently acquired by the KGS. Water was used as a drilling fluid. Borehole diameter was 3 in, and the cores, which were taken from approximately 20 ft below ground surface to total depth, were NQ (2 in diameter) gauge. Kevin Bailey from GeoCertified, LLC (Shawnee, KS) donated time and instrumentation for analysis of mud gas during drilling. After reaching T.D., the well was logged behind pipe with a slim-hole natural gamma ray tool and cemented from T.D. to surface.

Cores were described at the wellsite (Appendix 1) and photographs were taken of each core box (Appendix 2).

Coal and dark shales selected for desorption testing were collected in canisters that were supplied by the Kansas Geological Survey. Lag times for samples to reach the surface (important for assessing lost gas) were determined by noting the time, to the nearest 15 seconds, when the samples were taken off-bottom, when they reached the surface, and when they were canistered.

Cores taken for desorption were immersed in water. Zephryn chloride or isopropyl alcohol was added as a biocide, with a headspace of 1 to 2 inches being preserved at the top of the canister. Temperature baths were available on site.

All samples were transported to the laboratory at the Kansas Geological Survey in Lawrence, Kansas, on a daily basis, and desorption measurements were continued at approximately 70°F (the approximate formation temperature at depth). Desorption measurements were periodically made until the canisters produced negligible gas with daily testing for at least two successive days, or if the canisters were still degassing, they were ultimately decanistered in the last week of July 2010, approximately one year after they were canistered at wellsite. This date was chosen because it was the last week of the grant duration.

Selected samples of desorption gas were collected in 120-cc vaccination bottles sent to Isotech Laboratories in Champaign, Illinois, for analysis. Gas samples were collected in these glass containers by a capillary tube connected to the desorption canister, using the internal pressure of the canister to force the gas out of the canister. The sampling container was filled with water and inverted and immersed in a water-filled bucket. Gas bubbled from the capillary tube then displaced this water out of the sampling container. The container was sealed under water.

Upon decanistering, the samples were weighed in the laboratory for a wet weight. The sample was halved and both halves were weighed again. One half of the sample was dried in air for several weeks and weighed for a dry weight, and then archived. Part of one sample (i.e., Drywood coal, 1193' 2.5" to 1194' 8.5"—the coal desorbing the greatest amount of gas) was crushed in a ball mill for a residual gas measurement. If the sample that was crushed for residual gas was only one day or less out of the canister, the residual gas from it was proportioned to the wet weight of the entire sample. If the sample that was crushed for residual gas was a dry sample, the residual gas was proportioned to the dry weight of the entire sample.

The volumetric capacity of the ball mill used for the residual gas determination was approximately 2500 ccs. The sample selected for residual gas was weighed before being placed in the ball-mill canister. Immediately before the sample was sealed in the ball-mill canister, the canister was flooded with helium so that any atmospheric oxygen that may oxidize the sample was thus removed. The sample was crushed approximately 24 hours, and after removal from the ball mill, the canister was allowed to equilibrate to laboratory temperature. The temperature and atmospheric pressure was noted at the time the canister was sealed and when the residual gas was finally measured. Corrections (5 ccs for every degree F change in temperature; 2.7 ccs for every mb change in atmospheric pressure) were applied to the gas measured from the canister. Results for the residual gas analyses are reported in the desorption tables for the well (Table 1).

Proximate analyses were performed on selected samples by Luman's Laboratories in Chetopa, Kansas. Results of the proximate analyses are reported in the desorption tables for the well (Table 1).

Density measurements for each sample were also made after each sample was dried. Core samples were weighed and then immersed in water in a beaker filled to its brim. Placing the sample in the beaker caused the

displaced water to spill from the beaker into another container. This displaced water was subsequently weighed. The weight of the water displaced by the sample is thus easily converted to volume by using 1 gram/cc for the density of the water. Results for the density measurements are reported in the desorption tables for each well (Table 1).

Correlation of the core and nearby wells cored in Franklin County, Kansas (Colt Energy #2-6 Spencer) and Bates County, Missouri (Petron Resources #1-24 Jacobs) is facilitated by a stratigraphic cross section in Appendix 3. Gamma-ray logging for the core hole is also presented on this diagram, as well as desorption analyses and identification of stratigraphic units.

Gas Detection

Kevin Bailey from GeoCertified, LLC (Shawnee, Kansas) donated time and instrumentation for analysis of mud gas during drilling. The results, shown in Figure 2, show chromatograph and hotwire gas kicks are commonly associated with some of the deeper coal units. Conversely, a gas kick is associated with the Higginsville Limestone at 821 ft and an unnamed 7-ft sandstone at 917 ft depth. This sandstone has a 3-in coal overlying it, and perhaps some of the gas could have been derived from this coal. A scan of the original data received from GeoCertified, LLC is in Appendix 4.

Desorption Measurements

The equipment and method for measuring desorption gas is that prescribed by McLennan and others (1995). The volumetric displacement apparatus is a set of connected dispensing burettes, one of which measures the gas evolved from the desorption canister. The other burette compensates for the compression that occurs when the desorbed gas displaces the water in the measuring burette. This compensation is performed by adjusting the cylinders so that their water levels are identical, then figuring the amount of gas that evolved by reading the difference in water level using the volumetric scale on the side of the burette.

The desorption canisters were obtained from SSD, Inc., in Grand Junction, Colorado. These canisters are 12.5 in high (32 cm), 3.5 in (9 cm) in diameter, and enclose a volume of approximately 150 cubic inches (2450 cm³). The desorbed gas that collected in the desorption canisters was periodically released into the volumetric displacement apparatus and measured as a function of time, temperature, and atmospheric pressure.

The time and atmospheric pressure were measured in the field using a portable weather station (model BA928) marketed by Oregon Scientific (Tualatin, Oregon). The atmospheric pressure was displayed in millibars on this instrument.

A spreadsheet program written by K. D. Newell (Kansas Geological Survey) was used to convert all gas volumes at standard temperature and pressure. Conversion of gas volumes to standard temperature and pressure was by application of the perfect-gas equation, obtainable from basic college chemistry texts:

$$n = PV/RT$$

where n is moles of gas, T is degrees Kelvin (i.e., absolute temperature), V is in liters, and R is the universal gas constant, which has a numerical value depending on the units in which it is measured (for example, in the metric

system R = 0.0820 liter atmosphere per degree mole). The number of moles of gas (i.e., the value n) is constant in a volumetric conversion; therefore, the conversion equation, derived from the ideal gas equation, is:

$$(P_{\text{stp}} V_{\text{stp}})/(RT_{\text{stp}}) = (P_{\text{rig}} V_{\text{rig}})/(RT_{\text{rig}})$$

Customarily, standard temperature and pressure for gas volumetric measurements in the oil industry are 60°F and 14.7 psi (see Dake, 1978, p. 13), therefore P_{stp} , V_{stp} , and T_{stp} , respectively, are pressure, volume, and temperature at standard temperature and pressure, where standard temperature is degrees Rankine ($^{\circ}\text{R} = 460 + ^{\circ}\text{F}$). P_{rig} , V_{rig} , and T_{rig} , respectively, are ambient pressure, volume, and temperature measurements taken at the rig site or in the desorption laboratory.

The universal gas constant R drops out as this equation is simplified and the determination of V_{stp} becomes:

$$V_{\text{stp}} = (T_{\text{stp}}/T_{\text{rig}}) (P_{\text{rig}}/P_{\text{stp}}) V_{\text{rig}}$$

The conversion calculations in the spreadsheet were carried out in the English metric system, the customary measuring system used in American coal and oil industry. V is therefore converted to cubic feet; P is psia; T is $^{\circ}\text{R}$.

The desorbed gas was summed over the period for which the coal samples evolved all of their gas.

Lost gas (i.e., the gas lost from the sample from the time it was drilled, brought to the surface, to the time it was canistered) was determined using the direct method (Kissel and others, 1975; also see McLennan and others, 1995, p. 6.1-6.14) in which the cumulative gas evolved is plotted against the square root of elapsed time. Time zero is assumed to be instant the core sample is lifted from the bottom of the hole. Characteristically, the cumulative gas evolved from the sample, when plotted against the square root of time, is linear for a short time period after the sample reaches ambient pressure conditions; therefore, lost gas is determined by a line projected back to time zero. The period of linearity generally is about two hours for core samples.

Data Presentation

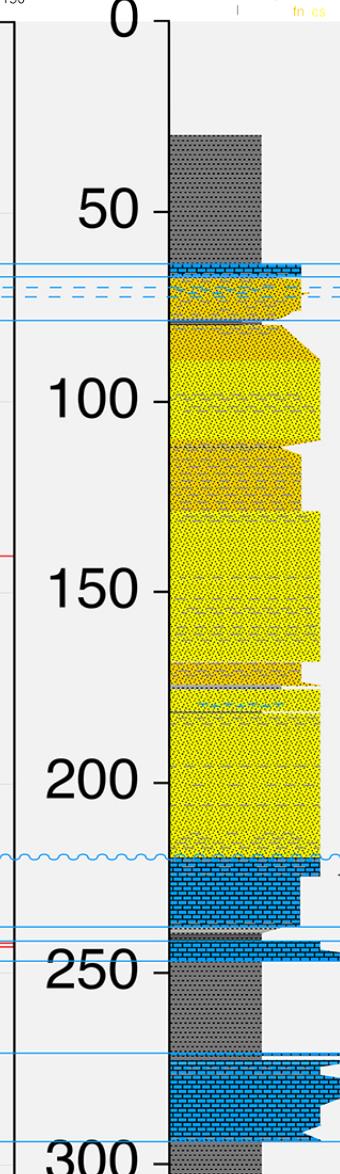

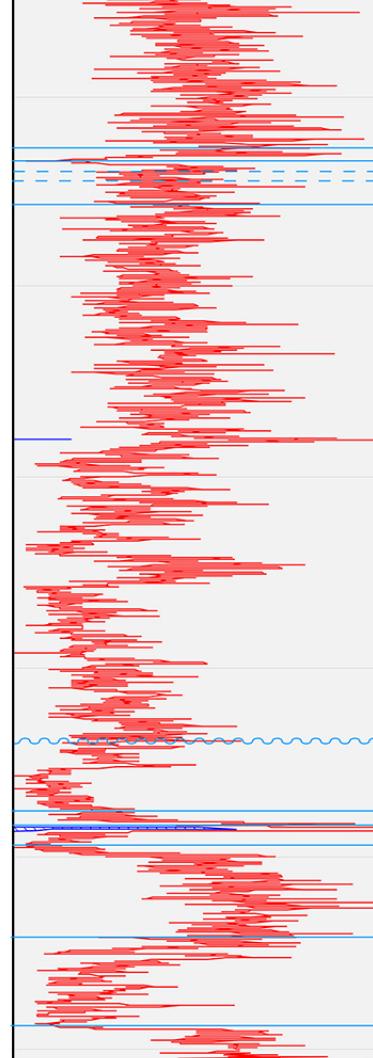

Desorption Analyses

The table showing the record of desorptions (Table 1) is the basic data used for lost-gas analysis and determination of total gas desorbed from the core samples. Wellsite descriptions and results from ashing and proximate analysis are presented in the headings for each sample. Basic temperature, volume, and barometric measurements are listed at left. Farther to the right, these are converted to standard temperature, pressure, and volumes. The volumes are cumulatively summed, and converted to scf/ton based on the total weight of coal and dark shale in the sample. At the right of the table, the time of the measurements are listed and converted to hours (and square root of hours) since the sample was drilled. Results for residual gas and drying are presented below the desorption data for each sample.

DECANISTERED 7/23/2010; sample dried for 3 days in air

SAMPLE: 1192' 0" to 1193' 2.5" (Drywood coal) core in SSD canister 80

density = 1.51 grams/cc

PROXIMATE ANALYSIS by Luman's Laboratories, Chetopa, KS

DECANISTERED 7/23/2010; sample dried for 3 days in air; 242.82 grams of sample ground in ball mill. 107.19 ccs @ stp released, which is proportional to 574.42 ccs residual gas for 1240.08 grams of dry sample

SAMPLE: 1201' 0" to 1202' 5.5" (Rowe coal) core in SSD canister
density = 1.32 grams/cc

DECANISTERED 7/23/2010; sample dried for 3 days in air

SAMPLE: 1675' 0" to 1676' 0" (Chattanooga Shale) core in SSD canister
density = 2.47 grams/cc

DECANISTERED 7/22/2009 discontinued due to no appreciable gas generated

Lost-Gas Determinations

Gas lost prior to the canistering of the sample was estimated by extrapolation of the first few data points after the sample was canistered. The linear characteristic of the initial desorption measurements was usually lost within the first two hours after canistering; thus, data are presented in the lost-gas graphs for only up to nine hours after canistering. Lost-gas volume determined for each sample (see Figure 3) is incorporated in the data table described above (see Table 1).

Desorbed Gas

The coal desorption graphs (Figure 4) are all at a common scale and are presented by specific coals, from shallowest to deepest in the well. These coals are also compared to stratigraphically correlative coals in the nearby Colt Energy #2-6 Spencer well (sec. 6, T. 18 S., R. 21 E., Franklin Co., Kansas). The gas contents in all the coals from the #1 Douglas County Core Hole are substantially less than the coals in the Spencer well.

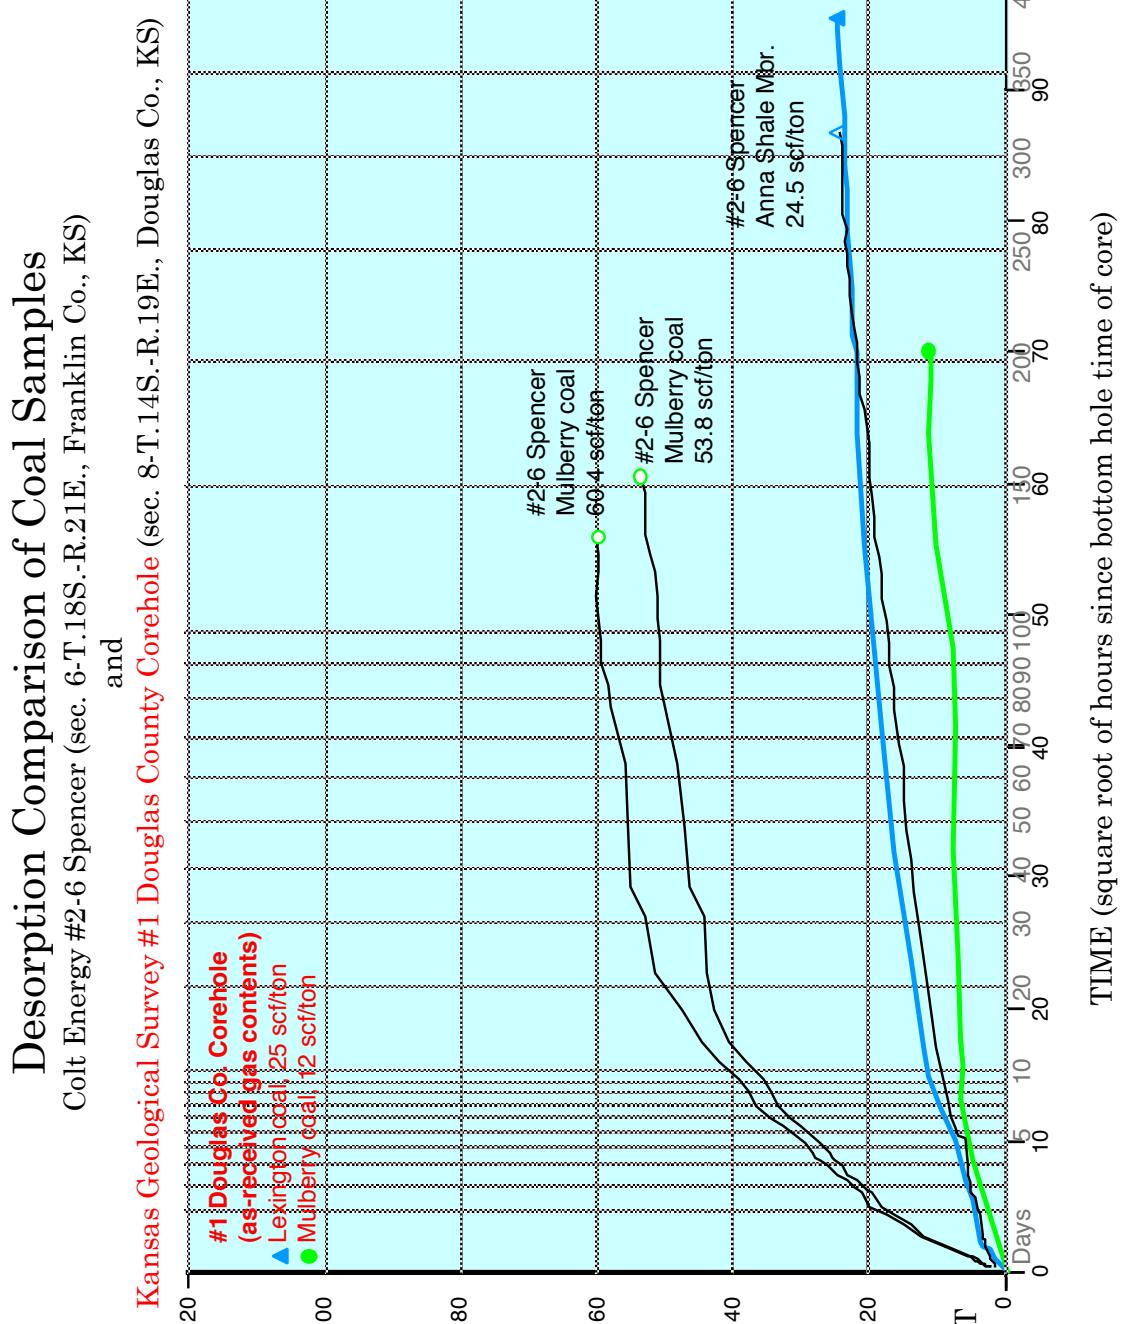

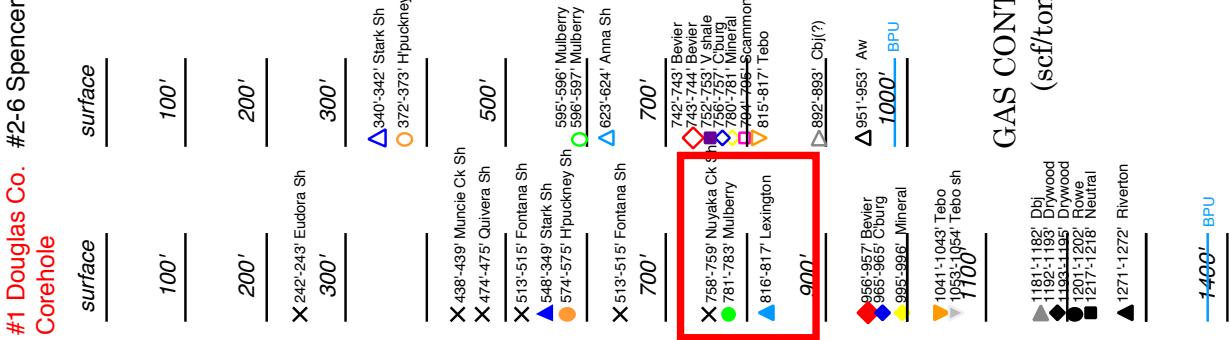

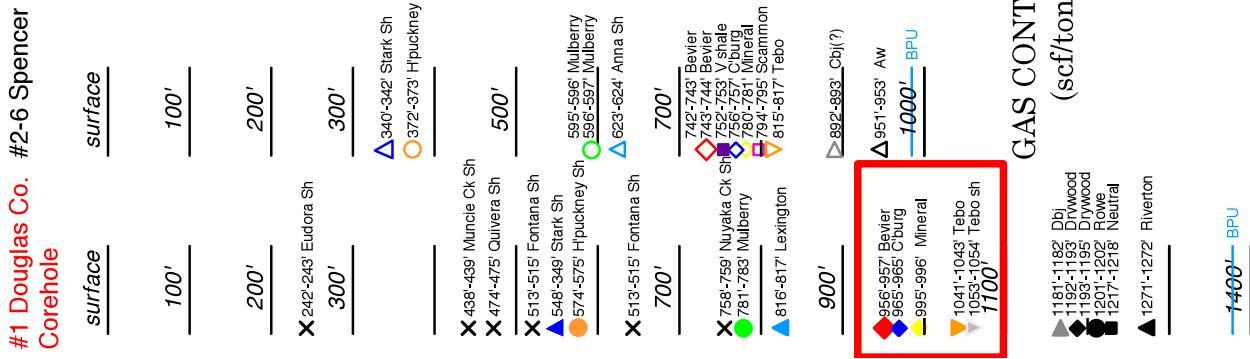

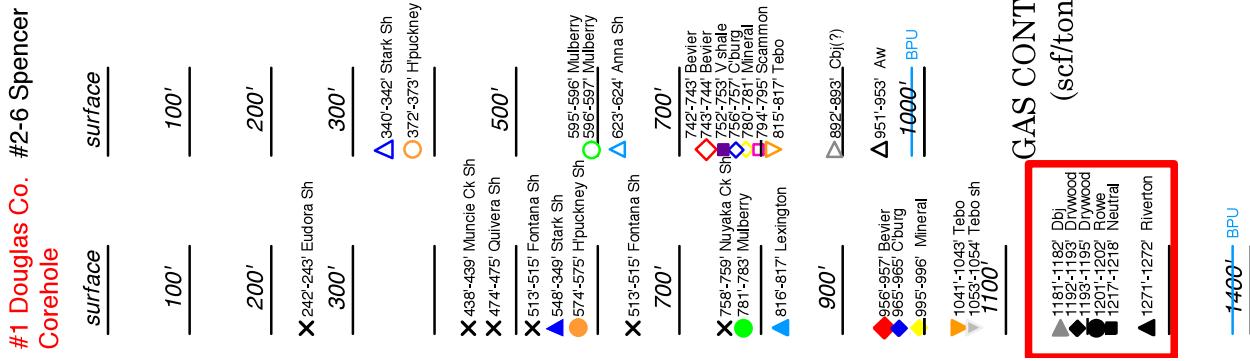

Figure 4a—Desorption characteristics of coals in upper part of hole (700-900 ft).

Desorption Comparison of Coal Samples
Colt Energy #2-6 Spencer (sec. 6-T.18S.-R.21E., Franklin Co., KS)

FIGURE 4c.

Ash content and proximate analysis allows for determination of ash-free gas content of samples and rank of the coals by the Parr Formula (see ASTM, 1993, p. 202) (Table 2).

Table 2—Desorbed gas content on an as-received and ash-free basis, with calculated coal rank for samples with less than 50% ash content.

SAMPLE	As-received gas content (scf/ton)	Ash-free gas content (scf/ ton)	Ash Content (as-received) (%)	Moisture Content (as-received) (%)	Coal Rank
Stark Shale Mbr., 548' 0"	negligible	negligible	68.27	2.62	
Hushpuckney Sh. Mbr., 573' 9.5"	10.9	41.7	68.93	2.84	
Nuyaka Ck. sh., 757' 6"	8.5	33.2	69.72	2.80	
Mulberry, 816' 2"	11.2	15.4	19.57	6.10	hvCb
Lexington, 371' 2"	25.1	33.1	13.71	9.08	hvCb
Bevier, 955' 8"	9.7	21.8	48.79	4.53	hvBb
Croweburg, 965' 8"	18.2	23.8	16.62	5.97	hvBb
Mineral, 995' 0"	19.4	32.4	33.58	4.92	hvBb
Tebo, 1041' 5"	21.0	35.0	33.38	4.87	hvBb
DBj, 1180' 6"	34.2	54.6	33.92	2.56	hvBb
Drywood, 1192' 0"	44.6	69.0	20.25	3.26	hvBb
Drywood, 1193' 2.5"	55.4	61.2	15.43	3.76	hvBb
Rowe, 1201' 0"	50.8	61.2	10.45	5.90	hvBb
Neutral, 1217' 2.5"	34.4	43.1	14.67	4.68	hvBb
Riverton, 1271' 1"	38.7	50.2	19.06	3.13	hvBb

hvBb = high-volatile bituminous B

hvCb = high-volatile bituminous C

Based on these analyses, most coals in the #1 Douglas County Core Hole assay along the boundary between high-volatile bituminous B and C ranks.

Gas Chemistry

Gas isotopic chemistry from the #1 Douglas County Core Hole is crossplotted and compared to other nearby gases (Figure 5). Based on these data, the origin of the gas in the #1 Douglas County Core Hole is biogenic in origin. A sample of desorption gas from the Nuyaka Creek shale (757' 6" to 759' 2") is isotopically very light— $-73.04\delta^{13}\text{C}_1$, comparable to a Hushpuckney Shale Member (424 ft) sample from northern Anderson County (i.e., $-72.44\delta^{13}\text{C}_1$). The methane in the deeper samples of the #1 Douglas County Core Hole is slightly less depleted (i.e., less negative), hence thermogenesis may account for a small amount of the methane in these deeper samples. The isotopic chemistry of the gases is shown in Table 3.

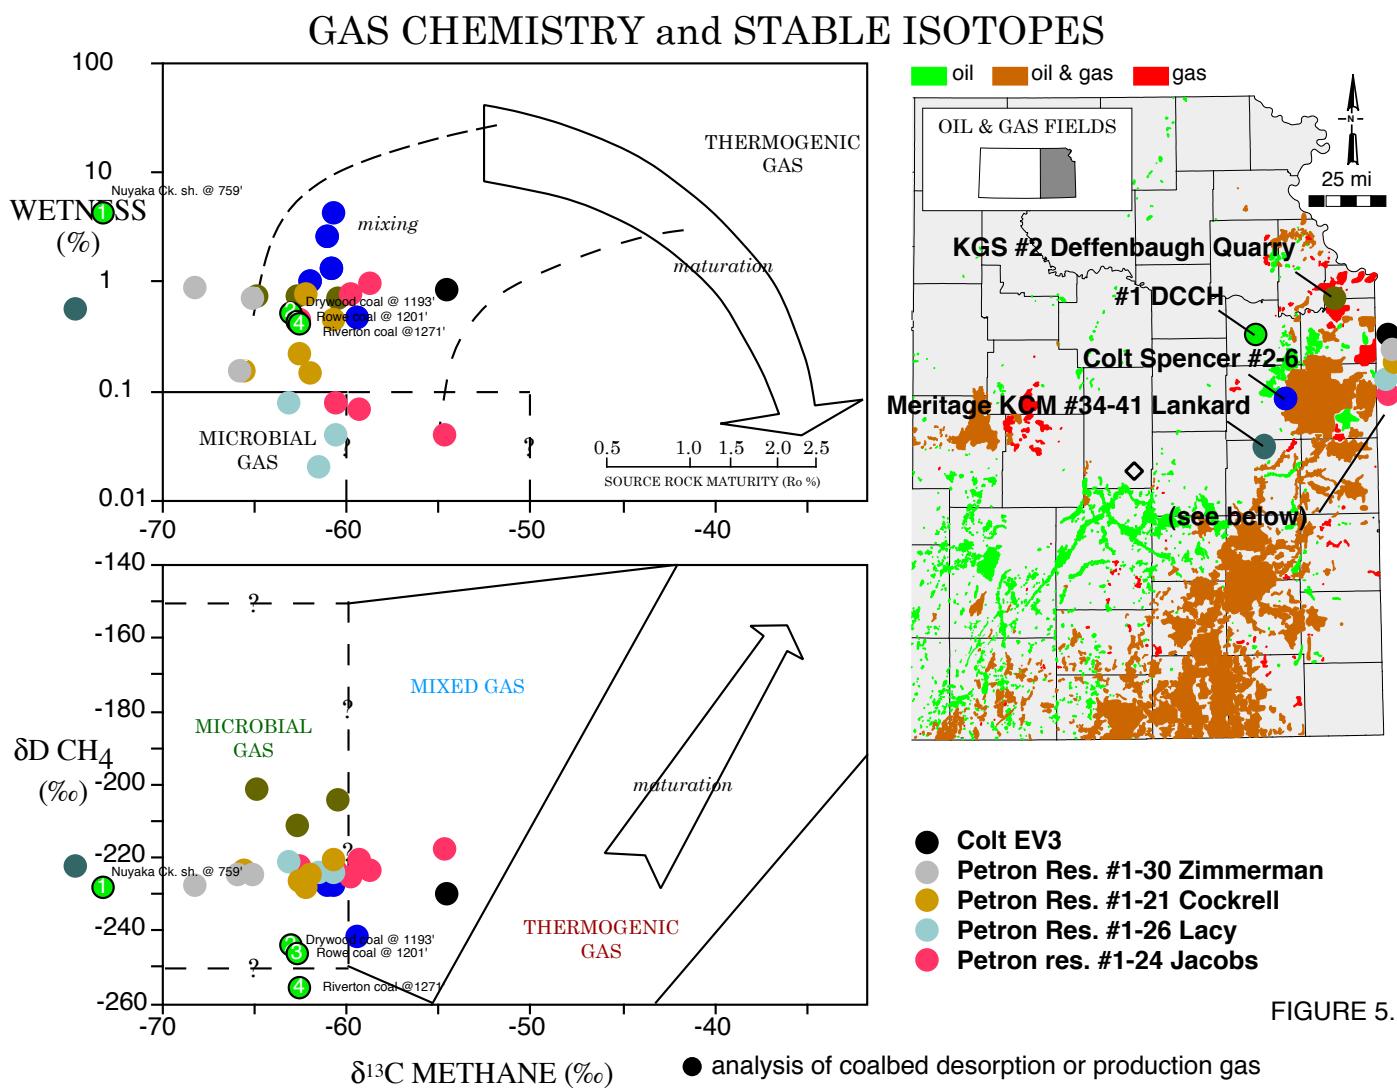

FIGURE 5.

Figure 5—Isotope and chemistry cross-plot for desorption gases from #1 Douglas County Core Hole and desorption gases from the nearby Colt Energy #2-6 Spencer well.

Table 3—Isotopes of the Douglas County Core Hole gases.

SAMPLE	$\delta^{13}\text{CO}_2$ per mil	$\delta^{13}\text{C1}$ per mil	δDC1 per mil	$\delta^{13}\text{C2}$ per mil	$\delta^{13}\text{C3}$ per mil
Nuyaka Ck. sh. 757' 6" - 759' 2"	-20.14	-73.04	-228.6	-40.83	-33.93
Drywood coal 1193' 2.5" - 1194' 8.5"	-11.86	-62.99	-243.7	-31.71	
Rowe coal 1201' 0" - 1202' 5.5"	-9.34	-62.55	-246.1	-31.29	
Riverton coal 1271' 1" - 1271' 8"	-16.46	-62.50	-255.3	-31.23	

Raw (i.e., uncorrected for atmosphere) hydrocarbon percentages for the desorbed gases are in Table 4.

Table 4a—Raw hydrocarbon percentages in the desorbed gases.

Sample	methane (%)	ethane (%)	propane (%)	n-butane (%)	Iso-butane (%)	n-pentane (%)	so-pentane (%)	hexane + (%)
Nuyaka Ck. shale 717' 6" - 718' 6"	54.94	1.37	0.733	0.113	0.0260	0.0125	0.0260	0.0132
Drywood coal 1193' 2.5" - 1194' 8.5"	72.56	0.385	0.0014	0.0006	0.0005	0.0002	0.0002	0.0002

Riverton coal 1271' 1" - 1271' 8"	40.94	0.161	0.0025	0.0006	0.0005	0.0004	0.0004	0

Table 4b—Raw non-hydrocarbon percentages in the desorbed gases.

SAMPLE	nitrogen (%)	oxygen (%)	argon (%)	carbon dioxide (%)	helium (%)
Nuyaka Ck. sh. 717' 6" - 718' 6"	41.73	0.15	0.415	0.28	0.0775
Drywood coal 1193' 2.5" - 1194' 8.5"	25.71	0.33	0.244	0.71	0.0550
Rowe coal 1201' 0" - 1202' 5.5"	30.13	0.53	0.302	1.50	0.0410
Riverton coal 1271' 1" - 1271' 8"	56.30	0.95	0.639	0.98	0.0296

Recalculating the component gases minus any contribution by air entails using the volume of oxygen in each sample and using the ratios of the other atmospheric gases to oxygen. The composition of dry atmosphere was taken to be that stated in Weaver (1966). The percentage of air by volume according to Weaver (1966): nitrogen, 78.00; oxygen, 20.95; argon, 0.93; carbon dioxide, 0.03; neon, 0.0018; helium 0.0005; methane, 0.0002; krypton, 0.0001; nitrous oxide, 0.00005; hydrogen, 0.00005; xenon, 0.000008; ozone, 0.000001.

The percentages (recalculated to 100% and two decimal places) of component gases in the samples, without air, are in Table 5. Helium percentage is presented to four decimal places.

Table 5—Recalculated percentages of component gases, excluding atmosphere. Based on the above percentages, gas quality can be calculated by the atmosphere-out gas percentages and the BTU content of the hydrocarbon component gases (see Table 6).

SAMPLE	C1 (%)	C2 (%)	C3 (%)	n-C4 (%)	i-C4 (%)	n-C5 (%)	i-C5 (%)	C6+ (%)	N ₂ (%)	Ar (%)	CO ₂ (%)	He (%)
Nuyaka Ck. shale 717' 6" - 718' 6"	55.34	1.38	0.74	0.11	0.13	0.01	0.02	0.01	41.47	0.41	0.28	0.0781
Drywood coal 1193' 2.5" - 1194' 8.5"	73.72	0.39	0.00	0.00	0.00	0.00	0.00	0.00	24.87	0.23	0.72	0.0559
Rowe coal 1201' 0" - 1202' 5.5"	68.95	0.30	0.00	0.00	0.00	0.00	0.00	0.00	28.89	0.29	1.54	0.0421
Riverton coal 1271' 1" - 1271' 8"	42.88	0.17	0.00	0.00	0.00	0.00	0.00	0.00	55.26	0.63	1.03	0.0310

*Table 6—Heating value, total non-flammable gas percentages, and hydrocarbon wetness (i.e., $(1-[C1/\Sigma Cn]) * 100$).*

SAMPLE	calculated BTU (BTU/cubic ft)	total non-HC gas (%)	hydrocarbon wetness (%)
Nuyaka Ck. shale 717' 6" - 718' 6"	640	42.25	4.17
Drywood coal 1193' 2.5" - 1194' 8.5"	787	25.88	0.53
Rowe coal 1201' 0" - 1202' 5.5"	734	30.75	0.43
Riverton coal 1271' 1" - 1271' 8"	457	56.95	0.40

Total BTU was calculated using the following BTUs for each of the hydrocarbon component gases: methane (1057), ethane (1847), propane (2639), n-butane (3401), i-butane (3427), n-pentane (4204), i-pentane (4230), and hexane+ (4963).

The BTU calculations (Table 6) indicate that perhaps all the coals in the #1 Douglas County Core Hole may have low heat content unacceptable for sale to pipelines (i.e., nominally <950 BTU/scf is necessary for sale without penalty). Production would require upgrading to reject the nitrogen and, in some cases, removing carbon dioxide in addition to the nitrogen.

Adsorbed Gas-in-Place Calculation

Gas-in-place (GIP) is calculated based on desorption data—desorbed gas content (as-received), coal thickness, and coal density. The adsorbed GIP is presented by coal bed in Table 7. Coal beds with gas content less than 30 scf/ton were not considered. Any coal bed less than 10 inches thick was not considered in the summed gas-in-place.

Table 7—Gas-in-place for coals. Beds less than 10 inches thick, or 30 scf/ton are not considered.

Coal bed	Gas Content (scf/ton)	Density (grams/cc)	Thickness (inches)	Gas per Acre (cubic ft)
DBj, 1180' 6"	34.2	1.79	18	124,858
Drywood, 1192' 0"	51.2*	1.39*	32.5	262,080
Rowe, 1201' 0"	50.8	1.32	17.5	132,966
Neutral, 1217' 2.5"	34.4	1.35	8	(too thin)

*weighted average (14.5" @ 44.6 scf/ton, 18" @ 56.6 scf/ton; 14.5" @ 1.51 gr/cc, 18" @ 1.30 gr/cc)

Sorption Time

Sorption time, or the time necessary for 63.2% of the gas to desorb from a sample, is a relative measure of how readily gas will flow from a unit. Sorption times are illustrated in Figure 6 for the five coals in the #1 Douglas County Core Hole (listed in Table 7). Desorbed gas content (as-received) and sorption time is crossplotted in an inset graph for the coals in the #1 Douglas County Core Hole of the coal units in this well (Figure 6). For comparison, two deep coals from the Colt Energy #2-6 Spencer well are also added to the graphs in Figure 6. The comparatively longer sorption times (and lesser gas contents) are likely due to the lesser coal ranks at the #1 Douglas County Core Hole.

Isotherm

A methane isotherm was performed on one sample—the lower part of the Drywood coal (1193' 2.5" to 1194' 8.5") by TerraTek (a division of Schlumberger) in Salt Lake City, Utah. The methane isotherm for this coal is presented in Figure 7, together with a data point depicting the pressure and gas content state of the Drywood coal in the #1 Douglas County Core Hole. This data point is determined by the crossplotted point of the total gas content for the Drywood coal (77 scf/ton) and its present formation pressure (568 psi). The gas content (77 scf/ton) is the sum of the desorbed gas content and residual gas (see calculations in Table 1). Residual gas was determined by ball-mill grinding after desorption; see Table 1). The inferred pressure (568 psi) was calculated by multiplying the subsurface depth (1193 ft) times a 0.476 psi/ft hydrostatic gradient. This hydrostatic gradient was determined by Carr and others (2005) for an average brine (145,000 ppm) in Kansas.

The Drywood coal is undersaturated in that the coal contains considerably less adsorbed gas than it is

capable of holding, according to its isotherm (see Figure 7). In order to start this coal desorbing, the ambient pressure on it has to be reduced to at least 161 psi, which is equivalent to pumping down the well until there is less than 338 ft of water above the coal.

Results and Discussion

Coal beds in the #1 Douglas County Core Hole were encountered between 268 ft and 705 ft depth. In this part of the Bourbon arch, regional dip is to the northwest at 10 to 20 ft per mile (Johnson, 2004).

The thickest coal beds were the Drywood (32.5 in), Tebo (18 in), Rowe (17.5 in), Mulberry (17 in), Bevier (13 in), Dbj (12 in), and Lexington (12 in). The Drywood coal, by virtue of its gas content (~57 scf/ton, as received) and thickness, holds the greatest adsorbed gas-in-place per acre of all the coals encountered.

The gas contents of the coal beds encountered in the well are low compared to coal in southeastern Kansas. Southeastern Kansas coals have a median as-received gas content of 139 scf/ton and samples with gas content as great as 370 scf/ton have been recorded (Newell and Carr, 2009). By comparison, the Drywood coal sample registering the greatest gas content in the #1 Douglas County Core Hole (57 scf/ton) ranks in the bottom

10% of all samples recorded in southeastern Kansas.

Gas in the coals at the #1 Douglas County Core Hole originated largely biogenic and to a smaller extent, mixed biogenic-thermogenic processes. Most coals are borderline in rank between high-volatile C bituminous and high-volatile B bituminous grades. Gas contents of coal at this locality were less than in other wells analyzed nearby in the Forest City basin to the south and southeast. Coals at the nearby Colt Energy #2-6 Spencer well in Franklin County are generally more thermally mature—high-volatile B and high-volatile A bituminous grades. This lesser maturity at the #1 Douglas County Core Hole could account for comparatively a) lesser gas content in its coals, b) longer sorption times, and c) lesser hydrocarbon gas content in its coals and shales.

The comparatively low thermal maturation at the #1 Douglas County Core Hole is somewhat of an anomaly, for equivalent strata farther southward and eastward higher on the flank of the Cherokee basin record higher coal rank, despite presently being 200 to 400 ft shallower. Lesser geothermal gradient at the #1 Douglas County Core Hole may be responsible, or alternatively, lesser thermal maturation may be due to cooling of northward-moving heated formation water derived from the deeper parts of Arkoma and Anadarko basins in Oklahoma.

Gas quality is less than 950 BTU/scf (i.e., nominal pipeline quality) for the three coals (Drywood, Rowe, and Riverton) sampled for gas chemistry. Excess nitrogen is the main culprit, but percentages of carbon dioxide in close to 1% may also dictate that some gas upgrading may be necessary before pipeline-quality gas can be sold. Upgrading would be necessary before the gas could be commercially sold.

Comparison of isotherms with gas content of the Drywood coal indicates that this coal is undersaturated with respect to its total capacity to hold gas. Dewatering of deeper coals will be necessary before these coals start desorbing gas.
